

# OpenTelemetry Fundamentals

**Series:** OTEL | **Notebook:** 1 of 8 | **Created:** January 2026 | **Last Updated:** 02/09/2026

## Introduction to OpenTelemetry and Dynatrace

OpenTelemetry (OTel) is the industry-standard framework for collecting telemetry data. Dynatrace fully supports OpenTelemetry through native OTLP ingestion, allowing you to leverage OTel instrumentation while benefiting from Dynatrace's AI-powered analytics.

## Table of Contents

- 1. [What is OpenTelemetry?](#)
- 2. [OTel vs. Proprietary Agents](#)
- 3. [Core Components](#)
- 4. [Signal Types: Traces, Metrics, Logs](#)
- 5. [Semantic Conventions](#)
- 6. [Dynatrace OTel Integration](#)
- 7. [When to Use OpenTelemetry](#)

## Prerequisites

| Requirement           | Details                                                                                   |
|-----------------------|-------------------------------------------------------------------------------------------|
| Dynatrace Environment | SaaS with OTLP ingestion enabled                                                          |
| Permissions           | <code>openpipeline.events</code> , <code>metrics.ingest</code> , <code>logs.ingest</code> |

| Requirement | Details                      |
|-------------|------------------------------|
| Knowledge   | Basic observability concepts |

# 1. What is OpenTelemetry?

OpenTelemetry is a vendor-neutral, open-source observability framework that provides:

| Component       | Purpose                                                  |
|-----------------|----------------------------------------------------------|
| APIs            | Standardized interfaces for instrumentation              |
| SDKs            | Language-specific implementations                        |
| Collector       | Agent for receiving, processing, and exporting telemetry |
| Protocol (OTLP) | Standard wire protocol for telemetry data                |

## CNCF Project

OpenTelemetry is a Cloud Native Computing Foundation (CNCF) project, formed from the merger of OpenTracing and OpenCensus. It's the second-most active CNCF project after Kubernetes.

## Key Benefits

| Benefit          | Description                                |
|------------------|--------------------------------------------|
| Vendor Neutral   | No lock-in to specific backends            |
| Standardized     | Consistent across languages and platforms  |
| Comprehensive    | Traces, metrics, and logs in one framework |
| Community-Driven | Active development, broad adoption         |

## 2. OTel vs. Proprietary Agents

---

### Comparison

| Aspect          | OpenTelemetry                  | Dynatrace OneAgent              |
|-----------------|--------------------------------|---------------------------------|
| Instrumentation | Manual or auto-instrumentation | Automatic                       |
| Deployment      | SDK + Collector                | Single agent                    |
| Coverage        | Code-level                     | Full-stack                      |
| Flexibility     | High (any backend)             | Dynatrace-specific              |
| Maintenance     | Higher                         | Lower                           |
| Features        | Standard signals               | AI, RCA, Dynatrace Intelligence |

### When to Choose OTel

| Scenario                     | Recommendation  |
|------------------------------|-----------------|
| Multi-vendor observability   | OTel            |
| Serverless/Lambda            | OTel            |
| Custom instrumentation needs | OTel            |
| Existing OTel investment     | OTel            |
| Full-stack visibility        | OneAgent + OTel |
| Minimal effort               | OneAgent        |

### Hybrid Approach

Dynatrace supports using both OneAgent and OTel together:

### 3. Core Components

#### OpenTelemetry Architecture

#### Component Descriptions

| Component | Role                                                     |
|-----------|----------------------------------------------------------|
| API       | Defines how to instrument (language-specific interfaces) |

| Component                        | Role                                           |
|----------------------------------|------------------------------------------------|
| <b>SDK</b>                       | Implements the API, handles sampling, batching |
| <b>Exporter</b>                  | Sends data to backends (OTLP, Jaeger, etc.)    |
| <b>Collector</b>                 | Standalone service for processing telemetry    |
| <b>Instrumentation Libraries</b> | Pre-built instrumentation for frameworks       |

## 4. Signal Types: Traces, Metrics, Logs

### Traces

Distributed traces track requests across services.

| Concept            | Description                            |
|--------------------|----------------------------------------|
| <b>Trace</b>       | End-to-end transaction path            |
| <b>Span</b>        | Single operation within a trace        |
| <b>SpanContext</b> | Propagated context (trace ID, span ID) |
| <b>Attributes</b>  | Key-value metadata on spans            |
| <b>Events</b>      | Timestamped annotations on spans       |

### Metrics

Quantitative measurements over time.

| Instrument Type      | Use Case                       | Example                 |
|----------------------|--------------------------------|-------------------------|
| <b>Counter</b>       | Monotonically increasing value | Request count           |
| <b>UpDownCounter</b> | Value that goes up and down    | Active connections      |
| <b>Histogram</b>     | Distribution of values         | Response time           |
| <b>Gauge</b>         | Current value                  | Temperature, queue size |

# Logs

Structured event records correlated with traces.

| Field        | Description                    |
|--------------|--------------------------------|
| Timestamp    | When the event occurred        |
| Severity     | Log level (DEBUG, INFO, ERROR) |
| Body         | Log message content            |
| Attributes   | Structured metadata            |
| TraceContext | Link to active span            |

## 5. Semantic Conventions

Semantic conventions define standard attribute names for consistent telemetry.

**Note:** OpenTelemetry semantic conventions are evolving. HTTP conventions were **stabilized in 2023** with new names (see migration tables below). Database conventions are also migrating. SDKs support a gradual transition via the `OTEL_SEMCONV_STABILITY_OPT_IN` environment variable. Both old and new names may coexist during migration.

### Resource Attributes

| Attribute                                | Example                   | Description            |
|------------------------------------------|---------------------------|------------------------|
| <code>service.name</code>                | <code>checkout-api</code> | Logical service name   |
| <code>service.version</code>             | <code>1.2.3</code>        | Service version        |
| <code>service.namespace</code>           | <code>production</code>   | Service namespace      |
| <code>deployment.environment.name</code> | <code>prod</code>         | Deployment environment |

**Note:** `deployment.environment` was renamed to `deployment.environment.name` in

the stable resource semantic conventions.

## HTTP Span Attributes

| Old (Legacy)                  | Stable                                          | Description                |
|-------------------------------|-------------------------------------------------|----------------------------|
| <code>http.method</code>      | <code>http.request.method</code>                | HTTP method                |
| <code>http.url</code>         | <code>url.full</code>                           | Full URL                   |
| <code>http.status_code</code> | <code>http.response.status_code</code>          | Response status code       |
| <code>http.route</code>       | <code>url.path</code> / <code>http.route</code> | URL path or route template |
| <code>http.target</code>      | <code>url.path</code> + <code>url.query</code>  | Request target             |
| <code>http.host</code>        | <code>server.address</code>                     | Server hostname            |

**Tip:** Use `OTEL_SEMCONV_STABILITY_OPT_IN=http` to emit only stable names, or `http/dup` to emit both old and new during migration. See the [HTTP semconv migration guide](#).

## Database Span Attributes

| Old (Legacy)              | Stable                         | Description               |
|---------------------------|--------------------------------|---------------------------|
| <code>db.name</code>      | <code>db.namespace</code>      | Database name/namespace   |
| <code>db.statement</code> | <code>db.query.text</code>     | Query statement           |
| <code>db.operation</code> | <code>db.operation.name</code> | Operation type            |
| <code>db.system</code>    | <code>db.system</code>         | Database type (unchanged) |

**Tip:** Use `OTEL_SEMCONV_STABILITY_OPT_IN=database` for stable database names. See the [DB semconv migration guide](#).

## Kubernetes Attributes

| Attribute                        | Example                          | Description |
|----------------------------------|----------------------------------|-------------|
| <code>k8s.namespace.name</code>  | <code>checkout</code>            | Namespace   |
| <code>k8s.pod.name</code>        | <code>checkout-api-abc123</code> | Pod name    |
| <code>k8s.deployment.name</code> | <code>checkout-api</code>        | Deployment  |

## 6. Dynatrace OTel Integration

### OTLP Endpoints

Dynatrace accepts OTLP data natively via **HTTP only** (gRPC is not supported for direct ingest):

| Protocol    | Endpoint                                                       | Notes                                  |
|-------------|----------------------------------------------------------------|----------------------------------------|
| <b>HTTP</b> | <code>https://{your-env}.live.dynatrace.com/api/v2/otlp</code> | Recommended for direct ingest          |
| <b>gRPC</b> | Not supported for direct Dynatrace ingest                      | Use a Collector to convert gRPC → HTTP |

**Important:** If your application uses gRPC to export OTLP data, route it through an OpenTelemetry Collector configured with an `otlp gRPC` receiver and an `otlphttp` exporter to Dynatrace. See [Transform OTLP gRPC](#).

### Authentication

Use Dynatrace API token with required scopes:

| Signal  | Required Scope                         |
|---------|----------------------------------------|
| Traces  | <code>openTelemetryTrace.ingest</code> |
| Metrics | <code>metrics.ingest</code>            |
| Logs    | <code>logs.ingest</code>               |

## Configuration Example

### OTel Collector Exporter:

```
exporters:
  otlphttp:
    endpoint: https://{your-env}.live.dynatrace.com/api/v2/otlp
    headers:
      Authorization: Api-Token ${DT_API_TOKEN}
```

### SDK Direct Export (Python):

```
import os

from opentelemetry.exporter.otlp.proto.http.trace_exporter import
OTLPSpanExporter

exporter = OTLPSpanExporter(
    endpoint="https://{your-env}.live.dynatrace.com/api/v2/otlp/v1/traces",
    headers={"Authorization": f"Api-Token {os.environ['DT_API_TOKEN']}"}
)
```

```
// View OpenTelemetry traces in Dynatrace
fetch spans, from:-1h
| filter isNotNull(otel.library.name)
| fields timestamp, trace.id, span.name, otel.library.name, duration
| sort timestamp desc
| limit 20
```

```
// OTel instrumentation libraries in use
fetch spans, from:-1h
| filter isNotNull(otel.library.name)
| summarize count = count(), by:{otel.library.name, otel.library.version}
| sort count desc
| limit 20
```

## 7. When to Use OpenTelemetry

---

### OTel is Ideal For

| Scenario         | Why OTel                                 |
|------------------|------------------------------------------|
| Serverless       | AWS Lambda, Azure Functions (no agent)   |
| Multi-cloud      | Consistent instrumentation across clouds |
| Custom metrics   | Business-specific measurements           |
| Vendor diversity | Send to multiple backends                |
| Edge/IoT         | Lightweight collection                   |
| Polyglot         | Many languages, one standard             |

### OneAgent is Better For

| Scenario               | Why OneAgent                 |
|------------------------|------------------------------|
| Full-stack             | Infrastructure + code in one |
| Zero-effort            | Auto-instrumentation         |
| Dynatrace Intelligence | Full AI capabilities         |
| PurePath               | Complete transaction tracing |
| Real User Monitoring   | RUM integration              |

### Recommended: Hybrid

For most enterprises:

- **OneAgent** for infrastructure and supported technologies
- **OTel** for unsupported languages, serverless, custom metrics

## Next Steps

---

Now that you understand OTel fundamentals, proceed to:

| Next Notebook                          | Topic                        |
|----------------------------------------|------------------------------|
| <b>OTEL-02: Collector Architecture</b> | Deep-dive into the Collector |
| <b>OTEL-03: Collector Deployment</b>   | Deployment patterns          |
| <b>OTEL-04: Trace Instrumentation</b>  | Instrumenting your code      |

---

## Summary

In this notebook, you learned:

- What OpenTelemetry is and its benefits
- How OTel compares to proprietary agents
- Core OTel components: API, SDK, Collector
- Signal types: traces, metrics, logs
- Semantic conventions for consistent telemetry (including the stable HTTP and DB naming migration)
- Dynatrace OTLP integration configuration (HTTP only — gRPC requires Collector)
- When to use OTel vs. OneAgent

---
